ABSTRACT

The Korteweg–De Vries (KdV) equation has always provided a venue to study and generalizes diverse physical phenomena. The pivotal aim of the study is to analyze the behaviors of forced KdV equation describing the free surface critical flow over a hole by finding the solution with the help of $q$-homotopy analysis transform technique ($q$-HATT). The projected method is elegant amalgamations of $q$-homotopy analysis scheme and Laplace transform. Three fractional operators are hired in the present study to show their essence in generalizing the models associated with power-law distribution, kernel singular, non-local and non-singular. The fixed-point theorem employed to present the existence and uniqueness for the hired arbitrary-order model and convergence for the solution is derived with Banach space. The projected scheme springs the series solution rapidly towards convergence and it can guarantee the convergence associated with the homotopy parameter. Moreover, for diverse fractional order the physical nature have been captured in plots. The achieved consequences illuminates, the hired solution procedure is reliable and highly methodical in investigating the behaviours of the nonlinear models of both integer and fractional order.

1. Introduction

Mankind is always looking for innovation, development, novelty, modernization and modification in science and technology to lead daily life in a convenient manner. In this connection, mathematics is the basic, essential and pivotal tool and which aid us to study, investigate and predict the essence of life associated with surrounding nature. Among this tool, calculus with differential and integral operators is the most efficient and favourable instrument and it has been recanaled most elegant discipline. Most of the concept in nature associated with the rate of change, variation and modification are necessitates differential calculus. Recently, many researchers came with limitations of classical concept particularly to capture power-law, non-local, non-singular, heterogeneities, exponential decay, fading memory, fatigue effect, and other functions. Later, mathematicians suggested an old tool and which is rooted soon after the classical concept, called fractional calculus (FC). Many senior pioneers prearranged the reputation of FC and proposed distinct
For an incompressible and inviscid fluid, the two-bottom of the channel has some obstacles and dynamics of the free-surface waves. When the rigid bottom is more complex, the interplay between the bottom topography and solitary waves can demonstrate more stimulating dynamics of the free-surface waves. Similarly, authors derived interesting results for Calogero-Bogoyavlensky-Schif [26] and coupled Korteweg–de Vries equations [27] with similar techniques. To show the essence of the Lie symmetry analysis, authors in [28] investigated about the Bratu Gelfand model, the effect of fractional derivatives are illustrated by authors to capture the stimulating results associated with bipartite graph and fractional operator. The Lump and optical solitons solutions are derived by researchers in [35] with the analytical method, and authors in [36] derived some stimulating results associated with bipartite graph and fractional order. The projected method is hired by the scholars to investigate the system associated with Jaulent–Miodek system with energy-dependent Schrödinger potential [37], the epidemic model of childhood disease [38], liquids with gas bubbles models [39], the Zakharov–Kuznetsov equation in dusty plasma [40], and Degasperis-Procesi equations [41].

In a two-dimensional channel flow, the impact of bottom configurations on the free-surface waves is investigated with the help of the forced Korteweg-de Vries equation. The bottom topography plays a vital part in the study of shallow-water waves, and which can significantly evaluate the behaviours of wave motions [42, 43]. Shallow water or long waves are the waves in water shallower than 1/20 their actual wavelength. When the bottom configuration is more complex, the interplay between the bottom topography and solitary waves can demonstrate more stimulating dynamics of the free-surface waves. When the rigid bottom of the channel has some obstacles and for an incompressible and inviscid fluid, the two-dimensional channel flow with free surface waves have been studied [44, 45]. Fluid flows over an obstacle, the forcing approximately with the KdV equation can portray the development of the free surface. The FKdV equation is very important while describing the nature sine Gordon equation as well as the nonlinear Schrödinger equation. Further, the proposed model has numerous applications in the connected branches of mathematics and physics. This equation is considered an essential tool to study the propagation of short laser pulses in optical fibres, atmosphere dynamics, geostrophic turbulence and magnetohydrodynamic waves [46, 47]. Particularly, it offers stimulating results associated to physical problems such as acoustic waves on a crystal lattice, tsunami waves over obstacles, and shallow-water waves over rocks.

Here, we consider the forced KdV equation with the free water surface elevation measured \( u(x,t) \) on critical flow over a hole from undisturbed water level and which introduce and nurtured by Wu in 1987 [48], and presented as follows:

\[
\frac{1}{c} \frac{\partial u}{\partial t} + \left( F_r - 1 \right) - 3 \frac{u(x,t)}{h} \frac{\partial u}{\partial x} - \frac{h^2 \beta^2 u}{6 \partial x^3} = \frac{1}{f} \frac{\partial f(x)}{\partial x},
\]

(1)

where \( F_r \) is Froude number and it also calls as the critical parameter, \( h \) is the sea mean water depth, \( f(x) \) is the external forcing term and define as \( f(x) = \frac{p(x)}{pg} + b(x) \). Here, \( \frac{p(x)}{pg} \) is the surface air pressure, and \( b(x) \) is rigid bottom topography and is defined by \( b(x) = -0.1e^{-x^\beta} - 1 \). The Froude number \( F_r \) plays an important role in Eq. (1), since its value elucidates the kind of critical flows over the localised obstacle. Specifically, for \( > 1 \), \( = 1 \) and \( < 1 \) respectively represent the flow is considered as supercritical, trans-critical and subcritical. In the rigid bottom topography \( b(x) \), two different kinds of hole examined, namely for \( \beta = 2 \) and \( \beta = 8 \). The behaviours of \( b(x) \) for two distinct cases is cited in Figure 1. These cases respectively signify the hole is expected an inverse of bell-shaped and the hole is more flattened at the bottom as well as wider. Authors in [49], considered the simplified above equation by eliminating surface air pressure and presented it as follows

\[
\frac{1}{c} \frac{\partial u}{\partial t} + \left( F_r - 1 \right) - 3 \frac{u(x,t)}{h} \frac{\partial u}{\partial x} - \frac{h^2 \beta^2 u}{6 \partial x^3} = \frac{1}{h} \frac{\partial h(x)}{\partial x} = 0.
\]

(2)
In the literature, we have diverse fractional operators and the most familiarly used are including Riemann–Liouville (RL), Caputo [3], Caputo-Fabrizio (CF) [50] and Atangana–Baleanu (AB) [51] operators. However, mathematicians and scientists are always looking and searching for the tool which can help to derive and find the required consequences at a particular situation in specific context. In this regard, each earlier proposed concepts have their own confines. Including, the RL operator be unsuccessful to admit the universal truth of derivative and then M. Caputo suggested new notion which overcome this drawback. Recently, researchers cited some additional properties need to be incorporate with this operator and many new fractional operators with their own merits are suggested by mathematicians.

Recently, many researchers are hired them as generalizing tool to investigate diverse phenomena and achieved some stimulating consequences [6][16][18]. Particularly, these operators aid us to investigate the long-range memory, heterogeneity, exponential decay and non-local and non-singular, non-Gaussian without a steady-state and crossover behaviour. Now, we consider the fractional-order forced KdV (FF-KdV) equation by trading the time derivative with three fractional operators. Now, the FF-KdV equation is defined as follows

\[
D_\alpha^\nu u(x,t) = -c \left( \left( F_r - 1 \right) - \frac{3}{2} \frac{u(x,t)}{n} \right) \frac{\partial u}{\partial x} - \frac{h^2}{6} \frac{\partial^3 u}{\partial x^3} - \frac{1}{2} \frac{\partial b(x)}{\partial x} \right), \quad (3)
\]

\[
D_0^\alpha_{CF} u(x,t) = -c \left( \left( F_r - 1 \right) - \frac{3}{2} \frac{u(x,t)}{n} \right) \frac{\partial u}{\partial x} - \frac{h^2}{6} \frac{\partial^3 u}{\partial x^3} - \frac{1}{2} \frac{\partial b(x)}{\partial x} \right), \quad (4)
\]

\[
D_0^\alpha_{ABC} u(x,t) = -c \left( \left( F_r - 1 \right) - \frac{3}{2} \frac{u(x,t)}{n} \right) \frac{\partial u}{\partial x} - \frac{h^2}{6} \frac{\partial^3 u}{\partial x^3} - \frac{1}{2} \frac{\partial b(x)}{\partial x} \right), \quad (5)
\]

where \( 0 < \alpha \leq 1 \) is fractional-order. The considered model offers an interesting insight into diverse physical phenomena and hence it magnetizes researchers with different tools to present their viewpoints with corresponding derived consequences. For instance, authors in model [52] find the analytic solutions to the projected model; author in [53] presents some interesting result for the proposed model; considering the model for waves generated by topography, authors in [49][54] find the approximated analytical solution by using the HAM; authors in [55] investigated the considered problem and presented dynamics of trapped solitary waves; lines and pseudospectral solutions has been investigated by authors in [56].

The hired scheme is a blend of Laplace transform (LT) with homotopy based scheme [57][58]. The uniqueness of q-HATT is that it does not require assumptions, perturbations, conversion of nonlinear to linear and PDE to ODE [59]. Moreover, it is the generalization of many methods (results attained by this technique is a particular case for the value of parameters associated to method). The projected algorithm has been employed due to its efficiency and accuracy to examine the extensive classes of complex as well as nonlinear models and problems and also for the system of equations [60][67]. Recently, many interesting consequences are derived by using the projected scheme while analyzing the real-world problem.

The rest of the manuscript is systematized as follows: We followed the next section by basics and essential notions of both FC and LT. In Section 3, the solution for the hired model with three fractional operators are presented and also the existence and uniqueness of solutions with two fractional operators for the model is presented using Banach space within the frame of fixed-point theory. With the aid of attained outcomes and corresponding consequences, the discussion about the results is presented in Section 4 and finally, the concluding remarks on the present study are presented in the lost segment.

2. Preliminaries

Here, we recall few basic notions of FC [3][50][51][68][69]:

Definition 1. The Caputo fractional derivative of \( f \in C_{a-1}^n \) is presented for \( n \in \mathbb{N} \) as

\[
D_0^\alpha f(t) = \frac{d^n f(t)}{dt^n}, \quad \alpha = n \in \mathbb{N},
\]

\[
\frac{1}{\Gamma(n - \alpha)} \int_0^t (t - \vartheta)^{n-\alpha-1} f(\vartheta) d\vartheta, \quad n - 1 < \alpha < n. \quad (6)
\]

Definition 2. The fractional Caputo-Fabrizio (CF) derivative in Caputo sense for a function \( f \in H^1(a, b) (b > a) \) is presented as follows [68]

\[
D_0^\alpha_{CF} \left( f(t) \right) = \frac{\partial^\alpha f(t)}{\partial t^\alpha}, \quad (7)
\]

\[
M [\alpha] \left( M [0] = M [1] = 1 \right) \text{ is a normalization function.}
\]

Definition 3. The fractional Atangana-Baleanu-Caputo derivative for \( f \in H^1(a, b) (b > a) \) is
\[ a^{\alpha}_{ABC} D_t^\alpha (f(t)) \]
\[ = \mathcal{M} [\alpha] \int_a^t f'(\vartheta) E_\alpha \left[ -\frac{\alpha(t-\vartheta)\alpha}{1-\alpha} \right] d\vartheta. \quad (8) \]

**Definition 4.** The fractional AB integral is presented as
\[ a^{\alpha}_{AB} I_t^\alpha (f(t)) = \frac{1-\alpha}{\mathcal{M}[\alpha]} f(t) \]
\[ + \frac{\alpha}{\mathcal{M}[\alpha]} \int_0^t f(\vartheta) (t-\vartheta)^{\alpha-1} d\vartheta. \quad (9) \]

**Definition 5.** The Laplace transform (LT) for a Caputo fractional derivative \( D_t^\alpha f(t) \) is defined for \((n-1 < \alpha \leq n)\), as
\[ \mathcal{L} [D_t^\alpha f(t)] = s^\alpha F(s) - \sum_{r=0}^{n-1} s^{\alpha-r-1} f^{(r)} (0^+) \quad (10) \]
where \( F(s) \) is LT of \( f(t) \).

**Note:** According to [68], the following must hold
\[ \frac{2(1-\alpha)}{(2-\alpha) \mathcal{M}(\alpha)} + \frac{2\alpha}{(2-\alpha) \mathcal{M}(\alpha)} = 1, \quad 0 < \alpha < 1, (11) \]
which gives \( \mathcal{M}(\alpha) = \frac{2}{2-\alpha} \). By the assist of the above equation researchers in [68] proposed a novel Caputo derivative for \( 0 < \alpha < 1 \) as follows
\[ D_t^\alpha (f(t)) = \frac{1}{1-\alpha} \int_0^t f'(t) \exp \left[ -\frac{\alpha(t-\vartheta)}{1-\alpha} \right] d\vartheta. \quad (12) \]

**Definition 6.** The LT for a CF derivative \( \triangledown \) \( D_t^\alpha f(t) \) is presented as below
\[ \mathcal{L} \left[ D_t^\alpha f(t) \right] = s^{n+1} \mathcal{L}[f(t)] - s^n f(0) - s^{n-1} f'(0) - \ldots - f^n(0). \quad (13) \]

**Definition 7.** The LT of AB derivative is defined by
\[ \mathcal{L} \left[ a^{\alpha}_{AB} D_t^\alpha (f(t)) \right] = \frac{B[\alpha]}{1-\alpha} \left[ s^\alpha \mathcal{L}[f(t)] - s^\alpha f(0) \right]. \quad (14) \]

**Theorem 1.** The Lipschitz conditions for the RL and AB derivatives are respectively held the following results [51]
\[ \| a^{\alpha}_{AB} D_t^\alpha f_1(t) - a^{\alpha}_{AB} D_t^\alpha f_2(t) \| < K_1 \| f_1(x) - f_2(x) \|, \quad (15) \]
and
\[ \| a^{\alpha}_{AB} D_t^\alpha f_1(t) - a^{\alpha}_{AB} D_t^\alpha f_2(t) \| < K_2 \| f_1(x) - f_2(x) \|. \quad (16) \]

**Theorem 2.** The fractional-order differential equation \( a^{\alpha}_{ABC} D_t^\alpha f_1(t) = s(t) \) has a unique solution [51] and which is
\[ f(t) = \frac{1-\alpha}{B[\alpha]} s(t) \]
\[ + \frac{\alpha}{B[\alpha]} \int_0^t s(\zeta) (t-\zeta)^{\alpha-1} d\zeta. \quad (17) \]

### 3. Solution for FKDV equation

The considered solution procedure is presented for the FKDV equation with three fractional operators to find the series solution. Further, for both CF and AB fractional operators existence and uniqueness is derived with fixed point theory.

#### 3.1. Caputo Sense

Consider the equation defined in Eq. (3)
\[ D_t^\alpha u(x,t) + c \left( [F(t) - 1 - \frac{3}{2\pi}] \frac{du}{dx} \right) = 0, \quad (18) \]
with
\[ u(x,0) = -\frac{2e^x}{(1 + e^x)^2}. \quad (19) \]
Takinf \( LT \) on Eq. (18) and using Eq. (19), we get
\[ \mathcal{L}[u(x,t)] = \frac{1}{s} \left( -\frac{2e^{x}}{(1+e^{x})^{2}} \right) \tag{20} \]
\[ -\frac{1}{s} \mathcal{L} \left\{ (F_{r} - 1) - \frac{3}{2} \frac{\partial u}{\partial x} - \frac{h^{2}}{6} \frac{\partial^{3}u}{\partial x^{3}} - \frac{1}{2} \frac{\partial b(x)}{\partial x} \right\}. \]

Now, \( \mathcal{N} \) is presented as
\[ \mathcal{N}[\varphi(x,t;q)] = \mathcal{L}[\varphi(x,t;q)] - \frac{1}{s} \left( -\frac{2e^{x}}{(1+e^{x})^{2}} \right) \]
\[ + \frac{1}{s} \mathcal{L} \left\{ (F_{r} - 1) - \frac{3}{2} \frac{\varphi(x,t;q)}{h} \frac{\partial \varphi(x,t;q)}{\partial x} \right\} - \frac{h^{2}}{6} \frac{\partial^{3} \varphi(x,t;q)}{\partial x^{3}} - \frac{1}{2} \frac{\partial \varphi(x,t;q)}{\partial x}. \tag{21} \]

At \( \mathcal{H}(x,t) = 1 \), the deformation equation presented as
\[ \mathcal{L}[u_{m}(x,t) - k_{m}u_{m-1}(x,t)] = h\mathfrak{R}_{m}[u_{m-1}], \tag{22} \]
where
\[ \mathfrak{R}_{m}[u_{m-1}] = \mathcal{L}[u_{m-1}(x,t)] - \left( 1 - k_{m} \right) \frac{1}{s} \left( -\frac{2e^{x}}{(1+e^{x})^{2}} \right) \]
\[ + \frac{c}{s^{\alpha}} \mathcal{L} \left\{ (F_{r} - 1) - \frac{3}{2h} \sum_{i=0}^{m-1} u_{i} \frac{\partial u_{m-1-i}}{\partial x} \right\} - \frac{h^{2}}{6} \frac{\partial^{3}u_{m-1}}{\partial x^{3}} - \frac{1}{2} \frac{\partial b(x)}{\partial x}. \tag{23} \]

On employing inverse \( \mathcal{L} \) on Eq. (22), one can get
\[ u_{m}(x,t) = k_{m}u_{m-1}(x,t) + h\mathcal{L}^{-1} \{ \mathfrak{R}_{m}[u_{m-1}] \}. \tag{24} \]

On simplifying the above equations by assist of \( u_{0}(x,t) = -\frac{2e^{x}}{(1+e^{x})^{2}} \) we can evaluate terms of series
\[ u(x,t) = u_{0}(x,t) + \sum_{m=1}^{\infty} u_{m}(x,t) \left( \frac{1}{n} \right)^{m}. \tag{25} \]

as
\[ u_{1}(x,t) = \frac{h^{\alpha}}{\Gamma[\alpha+1]} \left( c \frac{6e^{2x}(1-e^{x})}{(1+e^{x})^{3}} h^{\alpha} \right. \]
\[ - \frac{e^{2x}(-1+11e^{x}-11e^{2x}+e^{3x})h^{2}}{3(1+e^{x})^{3}} - 0.025e^{-\frac{x^{2}}{4}} x \]
\[ + \left. \frac{2e^{x}(-1+e^{x})(-1+F_{r})}{(1+e^{x})^{3}} \right) \]
\[ : \]

3.2. Caputo-Fabrizio Sense

Consider the equation defined in Eq. (4) as
\[ C_{0}^{\alpha}D_{t}^{\alpha} u(x,t) = Q(x,t,u), \tag{31} \]
with initial conditions Eq. (19). Taking LT on Eq. (26) and by the assist of Eq. (19), we get
\[ \mathcal{L}[u(x,t)] = \frac{1}{s} \left( -\frac{2e^{x}}{(1+e^{x})^{2}} \right) - \frac{c}{s} (1-s) \alpha \]
\[ \mathcal{L} \left\{ (F_{r} - 1) - \frac{3}{2h} \frac{\partial u}{\partial x} - \frac{h^{2}}{6} \frac{\partial^{3}u}{\partial x^{3}} - \frac{1}{2} \frac{\partial b(x)}{\partial x} \right\}. \tag{27} \]

Now, \( \mathcal{N} \) is defined as
\[ \mathcal{N}[\varphi(x,t;q)] = \mathcal{L}[\varphi(x,t;q)] - \frac{1}{s} \left( -\frac{2e^{x}}{(1+e^{x})^{2}} \right) \]
\[ + c \frac{s+(1-s)\alpha}{s} \mathcal{L} \left\{ (F_{r} - 1) - \frac{3}{2} \frac{\varphi(x,t;q)}{h} \frac{\partial \varphi(x,t;q)}{\partial x} \right\} - \frac{h^{2}}{6} \frac{\partial^{3} \varphi(x,t;q)}{\partial x^{3}} - \frac{1}{2} \frac{\partial \varphi(x,t;q)}{\partial x}. \tag{28} \]

At \( \mathcal{H}(x,t) = 1 \), the deformation equation presented as
\[ \mathcal{L}[u_{m}(x,t) - k_{m}u_{m-1}(x,t)] = h\mathfrak{R}_{m}[u_{m-1}], \tag{29} \]
where
\[ \mathfrak{R}_{m}[u_{m-1}] = \mathcal{L}[u_{m-1}(x,t)] - \left( 1 - k_{m} \right) \frac{1}{s} \left( -\frac{2e^{x}}{(1+e^{x})^{2}} \right) \]
\[ \left. + \frac{c}{s^{\alpha}} \mathcal{L} \left\{ (F_{r} - 1) - \frac{3}{2h} \sum_{i=0}^{m-1} u_{i} \frac{\partial u_{m-1-i}}{\partial x} \right\} - \frac{h^{2}}{6} \frac{\partial^{3}u_{m-1}}{\partial x^{3}} - \frac{1}{2} \frac{\partial b(x)}{\partial x} \right\}. \tag{30} \]

Now, by the help of the initial condition, we can derive the terms of Eq. (19) as
\[ u_{1}(x,t) = h(1-\alpha+\alpha t)(c \frac{6e^{2x}(1-e^{x})}{(1+e^{x})^{3}} h^{\alpha} \]
\[ - \frac{e^{2x}(-1+11e^{x}-11e^{2x}+e^{3x})h^{2}}{3(1+e^{x})^{3}} - 0.025e^{-\frac{x^{2}}{4}} x \]
\[ + \left. \frac{2e^{x}(-1+e^{x})(-1+F_{r})}{(1+e^{x})^{3}} \right) \]
\[ : \]

Here, the existence and uniqueness are illustrated with \( \mathcal{C}_{0}^{\alpha} \) operator for the considered Eq. (26) as
\[ C_{0}^{\alpha}D_{t}^{\alpha} u(x,t) = Q(x,t,u), \tag{31} \]
Now, using Eq. (31) and results derived in [46], we obtained

\[
    u(x, t) - u(x, 0) = c_F \int_0^t \left\{-c \left[ (F_r - 1) - 3 \frac{u(x, t)}{h} \right] \frac{\partial u}{\partial x} - \frac{h^2}{6} \frac{\partial^3 u}{\partial x^3} - \frac{1}{2} \frac{\partial b(x)}{\partial x} \right\} ds,
\]

Then we have from [41] as follows

\[
    u(x, t) - u(x, 0) = 2 \frac{(1 - \alpha)}{M(\alpha)} Q(x, t, u) + \frac{2\alpha}{(2 - \alpha)M(\alpha)} \int_0^t Q(x, \zeta, u) d\zeta. \tag{33}
\]

**Theorem 3.** The kernel \( Q \) admits the Lipschitz condition and contraction if \( 0 \leq \left(c(F_r - 1) A - \frac{3}{4h} A (a_1 + a_2) - \frac{h^2}{6} A^3 - \frac{1}{2} \Lambda \xi \right) < 1 \) satisfies.

**Proof.** Consider the two functions \( A \) and \( A_1 \) to prove the theorem, then

\[
    \|Q(x, t, u) - Q(x, t, u_1)\| = \|c(F_r - 1) \frac{\partial}{\partial x} [u(x, t) - u(x, t_1)]
\]

\[
    = \left\{ - \frac{3}{2h} \left[ u(x, t) \frac{\partial u(x, t)}{\partial x} - u(x, t_1) \frac{\partial u(x, t_1)}{\partial x} \right] \right\} - \frac{h^2}{6} \frac{\partial^3 u}{\partial x^3} [u(x, t) - u(x, t_1)] - \frac{1}{2} \frac{\partial b(x)}{\partial x}
\]

\[
    \leq \|c(F_r - 1) \frac{\partial}{\partial x} [u(x, t) - u(x, t_1)]\| + \frac{3}{2h} \left[ u^2(x, t) - u^2(x, t_1) \right] - \frac{h^2}{6} \frac{\partial^3 u}{\partial x^3} [u(x, t) - u(x, t_1)] - \frac{1}{2} \frac{\partial b(x)}{\partial x}
\]

\[
    \leq \|c(F_r - 1) A - \frac{3}{4h} A [u(x, t) - u(x, t_1)]\| + \frac{h^2}{6} A^3 - \frac{1}{2} \frac{\partial b(x)}{\partial x} \|u(x, t) - u(x, t_1)\|
\]

\[
    \leq c(F_r - 1) A - \frac{3}{4h} A (a_1 + a_2)
\]

\[
    - \frac{h^2}{6} A^3 - \frac{1}{2} \frac{\partial b(x)}{\partial x} \|u(x, t) - u(x, t_1)\|, \tag{34}
\]

where \( a_1 = \|u\| \) and \( a_2 = \|u_1\| \) be the bounded function and \( b(x) = \xi \) is also a bounded function. Set \( \Psi = c(F_r - 1) A - \frac{3}{4h} A (a_1 + a_2) - \frac{h^2}{6} A^3 - \frac{1}{2} \Lambda \xi \) in Eq. (34), then

\[
    \|Q(x, t, u) - Q(x, t, u_1)\| \leq \Psi \|u(x, t) - u(x, t_1)\|. \tag{35}
\]

Eq. (35) provides the Lipschitz condition for \( Q \). Similarly, we can see that if \( 0 \leq c \left(F_r - 1) A - \frac{3}{4h} A (a_1 + a_2) - \frac{h^2}{6} A^3 - \frac{1}{2} \Lambda \xi \right) < 1 \), then it implies the contraction. By the assist of the above equations, Eq. (33) simplifies to

\[
    u(x, t) = u(x, 0) + \frac{2 (1 - \alpha)}{(2 - \alpha)M(\alpha)} Q(x, t, u) + \frac{2\alpha}{(2 - \alpha)M(\alpha)} \int_0^t Q(x, \zeta, u) d\zeta. \tag{36}
\]

Then we get the recursive form as follows

\[
    u_n(x, t) = \frac{2 (1 - \alpha)}{(2 - \alpha)M(\alpha)} Q(x, t, u_{n-1}) + \frac{2\alpha}{(2 - \alpha)M(\alpha)} \int_0^t Q(x, \zeta, u_{n-1}) d\zeta. \tag{37}
\]

Now, between the terms the successive difference is defined as

\[
    \phi_n(x, t) = u_n(x, t) - u_{n-1}(x, t)
\]

\[
    = \frac{2 (1 - \alpha)}{(2 - \alpha)M(\alpha)} (Q(x, t, u_{n-1}) - Q(x, t, u_{n-2}))
\]

\[
    + \frac{2\alpha}{(2 - \alpha)M(\alpha)} \int_0^t (Q(x, t, u_{n-1}) - Q(x, t, u_{n-2})) d\zeta. \tag{38}
\]

Notice that

\[
    u_n(x, t) = \sum_{i=1}^{n} \phi_i(x, t). \tag{39}
\]

Then we have

\[
    ||\phi_n(x, t)|| = ||u_n(x, t) - u_{n-1}(x, t)||
\]

\[
    = \left\| \frac{2 (1 - \alpha)}{(2 - \alpha)M(\alpha)} (Q(x, t, u_{n-1}) - Q(x, t, u_{n-2})) \right\|
\]

\[
    - Q(x, t, u_{n-2}) + \frac{2\alpha}{(2 - \alpha)M(\alpha)} \int_0^t (Q(x, t, u_{n-1}) - Q(x, t, u_{n-2})) d\zeta \tag{40}
\]
Let us consider \((43)\) is a solution for Eq. \((26)\), we consider and existence are verified. Now, to prove the Eq. \((26)\) will exist and unique. Further, if we have specific

\[
\text{Theorem 4. If we have specific } t_0, \text{ then the solution for Eq. } (26) \text{ will exist and unique. Further, we have}
\begin{align*}
\| \varphi_n (x, t) \| & = \| u_n (x, t) - u_{n-1} (x, t) \|
= \frac{2 (1 - \alpha)}{(2 - \alpha) M (\alpha)} \| Q (x, t, u_{n-1}) - Q (x, t, u_{n-2}) \|
+ \frac{2 \alpha}{(2 - \alpha) M (\alpha)} \left\| \int_0^t (Q (x, t, u_{n-1}) - Q (x, t, u_{n-2})) d\zeta \right\|.
\end{align*}
\]

The Lipschitz condition satisfied by the kernel \(t_1\), then

\[
\| \varphi_n (x, t) \| \leq \| u_n (x, t) - u_{n-1} (x, t) \|
= \frac{2 (1 - \alpha)}{(2 - \alpha) M (\alpha)} \| \varphi (n-1) (x, t) \|
+ \frac{2 \alpha}{(2 - \alpha) M (\alpha)} \| \varphi (n-1) (x, t) \| t \zeta.
\]

By the aid of the above result, we state the following result:

\[
\text{Let } u(x, t) \text{ is the bounded functions admitting the Lipschitz condition. Then, we get by Eqs. } (41) \text{ and } (42) \text{ is a solution for Eq. } (26)_, \text{ we consider}
\begin{align*}
\| u (x, t) - u (x, 0) \| & \leq \left[ \frac{2 (1 - \alpha)}{(2 - \alpha) M (\alpha)} \psi \right] \left[ \frac{2 \alpha}{(2 - \alpha) M (\alpha)} \right] ^n.
\end{align*}
\]

Therefore, for the obtained solution, continuity and existence are verified. Now, to prove the Eq. \((43)\) is a solution for Eq. \((26)\), we consider

\[
\begin{align*}
\| u (x, t) - u (x, 0) \| & = u_n (x, t) - K_n (t).
\end{align*}
\]

Let us consider

\[
\| K_n (t) \| = \| \frac{2 (1 - \alpha)}{(2 - \alpha) M (\alpha)} (Q (x, t, u) - Q (x, t, u_{n-1}))
+ \frac{2 \alpha}{(2 - \alpha) M (\alpha)} \int_0^t (Q (x, \zeta, u) - Q (x, \zeta, u_{n-1})) d\zeta \|
\leq \frac{2 (1 - \alpha)}{(2 - \alpha) M (\alpha)} \| (Q (x, t, u) - Q (x, t, u_{n-1}))
+ \frac{2 \alpha}{(2 - \alpha) M (\alpha)} \left\| \int_0^t (Q (x, \zeta, u) - Q (x, \zeta, u_{n-1})) d\zeta \right\|.
\]

This process gives

\[
\| K_n (t) \| \leq \left[ \frac{2 (1 - \alpha)}{(2 - \alpha) M (\alpha)} + \frac{2 \alpha}{(2 - \alpha) M (\alpha)} t \right] ^n.
\]

Similarly, at \(t_0\) we can obtain

\[
\| K_n (t) \| \leq \left[ \frac{2 (1 - \alpha)}{(2 - \alpha) M (\alpha)} + \frac{2 \alpha}{(2 - \alpha) M (\alpha)} t_0 \right] ^n M.
\]

As \(n \to \infty\), from Eq. \((46)\), \(\| K_n (t) \| \to 0\) provided \(\frac{2 (1 - \alpha)}{(2 - \alpha) M (\alpha)} + \frac{2 \alpha}{(2 - \alpha) M (\alpha)} t_0 < 1\). Next, for the solution of the projected model, we prove the uniqueness. Suppose \(u^*(x, t)\) is another solution, then

\[
u (x, t) - u^*(x, t)
= \frac{2 (1 - \alpha)}{(2 - \alpha) M (\alpha)} (Q (x, t, u) - Q (x, t, u^*))
+ \frac{2 \alpha}{(2 - \alpha) M (\alpha)} \int_0^t (Q (x, \zeta, u) - Q (x, \zeta, u^*)) d\zeta.
\]

Now, employing the norm on the above equation we get

\[
\| u (x, t) - u^* (x, t) \|
= \left\| \frac{2 (1 - \alpha)}{(2 - \alpha) M (\alpha)} (Q (x, t, u) - Q (x, t, u^*))
+ \frac{2 \alpha}{(2 - \alpha) M (\alpha)} \int_0^t (Q (x, \zeta, u) - Q (x, \zeta, u^*)) d\zeta \right\|
\leq \frac{2 (1 - \alpha)}{(2 - \alpha) M (\alpha)} \| u (x, t) - u^* (x, t) \|
+ \frac{2 \alpha}{(2 - \alpha) M (\alpha)} \left\| \int_0^t (Q (x, \zeta, u) - Q (x, \zeta, u^*)) d\zeta \right\|.
\]

On simplification

\[
\| u (x, t) - u^* (x, t) \|
\leq \frac{2 (1 - \alpha)}{(2 - \alpha) M (\alpha)} \| u (x, t) - u^* (x, t) \|
\leq \frac{2 \alpha}{(2 - \alpha) M (\alpha)} \Psi \leq 0.
\]

From the above condition, it is clear that \(u(x, t) = u^*(x, t)\), if
Now, by the help of the initial condition, we can with initial conditions (19). Taking LT on Eq. (51) and using Eq. (19), we have
\[
L[u(x, t)] = \frac{1}{s} \left( 1 - \frac{2 e^{\frac{x}{2}}}{1 + e^{x^2}} \right) - \frac{c}{B[\alpha]} \left[ (F_r - 1) - \frac{3 u(x, t)}{2 h} \frac{\partial u}{\partial x} \right] - \frac{h^2}{6} \frac{\partial^3 u(x, t)}{\partial x^3} - \frac{1}{2} \frac{\partial b(x)}{\partial x}.
\] (52)

Now, \( N \) is defined as
\[
N[\varphi(x, t; q)] = L[\varphi(x, t; q)] + \frac{1}{s} \left( \frac{2 e^{\frac{x}{2}}}{1 + e^{x^2}} \right) + \frac{c}{B[\alpha]} \left( 1 - \alpha + \frac{\alpha}{s^\alpha} \right) L \left\{ \left( F_r - 1 \right) - \frac{3 \varphi(x, t; q)}{2 h} \frac{\partial \varphi(x, t; q)}{\partial x} \right\} - \frac{h^2}{6} \frac{\partial^3 \varphi(x, t; q)}{\partial x^3} - \frac{1}{2} \frac{\partial b(x)}{\partial x}.
\] (53)

The deformation equation at \( \mathcal{H}(x, t) = 1 \), is given as follows
\[
L[u_m(x, t)] = k_m u_{m-1}(x, t) - k_m u_{m-1}(x, t),
\] (54)

where
\[
\mathcal{R}_m \left[ \tilde{u}^{m-1} \right] = L[u_m(x, t)] + \left( 1 - \frac{k_m}{n} \right) \left\{ \frac{1}{s} \left( \frac{2 e^{\frac{x}{2}}}{1 + e^{x^2}} \right) \right\} + \frac{c}{B[\alpha]} \left( 1 - \alpha + \frac{\alpha}{s^\alpha} \right) L \left\{ \left( F_r - 1 \right) \frac{\partial u_{m-1}}{\partial x} \right\} - \frac{3}{2h} \sum_{i=0}^{m-1} u_i \frac{\partial u_{m-1-i}}{\partial x} - \frac{h^2}{6} \frac{\partial^3 u_{m-1}}{\partial x^3} - \frac{1}{2} \frac{\partial b(x)}{\partial x}.
\] (55)

Now, by the help of the initial condition, we can derive
\[
\left( 1 - \frac{2(1-\alpha)}{(2-\alpha)M(\alpha)} \Psi - \frac{2^\alpha}{(2-\alpha)M(\alpha)} \Psi t \right) \geq 0.
\] (50)

Hence, Eq. (50) proves our required result. \( \square \)

### 3.3. Atangana-Baleanu Sense

Consider the equation defined in Eq. (5)
\[
\frac{\partial^\alpha u}{\partial x^\alpha} - \frac{h^2}{6} \frac{\partial^3 u}{\partial x^3} - \frac{1}{2} \frac{\partial b(x)}{\partial x} = 0, \quad 0 < \alpha \leq 1,
\] (51)

with initial conditions (19). Taking LT on Eq. (51) and using Eq. (19), we have
\[
\frac{\partial^\alpha u(x, t)}{\partial t^\alpha} = \mathcal{G}(x, t),
\] (56)

and the above equation is considered as
\[
\frac{\partial^\alpha u(x, t)}{\partial t^\alpha} = \mathcal{G}(x, t, u).
\] (57)

We have from Eq. (57) and Theorem 2
\[
u(x, t) - u(x, t) = \frac{1}{\mathcal{B}(\alpha)} \left[ \frac{3}{2h} \frac{\partial u(x, t)}{\partial x} - u(x, t) \frac{\partial u(x, t)}{\partial x} \right] - \frac{h^2}{6} \frac{\partial^3 u(x, t)}{\partial x^3} - \frac{1}{2} \frac{\partial b(x)}{\partial x}.
\] (58)

**Theorem 5.** The kernel \( \mathcal{G} \) admits the Lipschitz condition and contraction if \( 0 \leq \left( c \left( F_r - 1 \right) \delta - \frac{3}{4h} \delta (a + b) \right. \left. - \frac{h^2}{6} \delta^3 - \frac{1}{2} \delta \xi \right) < 1 \) satisfies.

**Proof.** To prove the theorem, let us consider the two functions \( u \) and \( u_1 \), then
\[
\| \mathcal{G}(x, t, u) - \mathcal{G}(x, t, u_1) \| \leq c \left( F_r - 1 \right) \delta - \frac{3}{4h} \delta \| u(x, t) - u(x, t_1) \| - \frac{h^2}{6} \| b(x) \| - \frac{1}{2} \delta \xi \| u(x, t) - u(x, t_1) \| \leq c \left( F_r - 1 \right) \delta - \frac{3}{4h} \delta (a + b) - \frac{h^2}{6} \delta^3 - \frac{1}{2} \delta \xi \| u(x, t) - u(x, t_1) \| \leq c \left( F_r - 1 \right) \delta - \frac{3}{4h} \delta (a + b) - \frac{h^2}{6} \delta^3 - \frac{1}{2} \delta \xi \| u(x, t) - u(x, t_1) \| \leq c \left( F_r - 1 \right) \delta - \frac{3}{4h} \delta (a + b) - \frac{h^2}{6} \delta^3 - \frac{1}{2} \delta \xi \| u(x, t) - u(x, t_1) \|
\] (59)

where \( a = \| u \|, b = \| u_1 \| \) (since \( u \) and \( u_1 \) are the bounded functions) and \( \| b(x) \| = \xi \) is also a bounded function. Putting \( \eta = u_1(x, t) = h \left( 1 - \alpha + \frac{\alpha t^{\alpha}}{\Gamma[\alpha + 1]} \right) \)
Plugging the norm on Eq. (63), and by the assist of forgoing relation, the Lipschitz condition is achieved for $G$. Further, we can see that if $0 \leq \left( \frac{2}{\alpha^2} \delta^2 + \lambda (a^2 + b^2 + ab) \right) < 1$, which leads to contraction. The recursive form of Eq. (60) is presented as

$$u_n (x, t) = \frac{(1 - \alpha)}{B(\alpha)} G(x, t, u_{n-1})$$

$$+ \frac{\alpha}{B(\alpha) \Gamma (\alpha)} \int_0^t G(x, \zeta, u_{n-1}) (t - \zeta)^{\alpha-1} d\zeta,$$

and initial condition

$$u(x, 0) = u_0 (x, t).$$

The successive difference between the terms is presented as

$$\phi_n (x, t) = u_n (x, t) - u_{n-1} (x, t)$$

$$= \frac{(1 - \alpha)}{B(\alpha)} (G_1(x, t, u_{n-1}) - G(x, t, u_{n-2}))$$

$$+ \frac{\alpha}{B(\alpha) \Gamma (\alpha)} \int_0^t G(x, \zeta, u_{n-1}) (t - \zeta)^{\alpha-1} d\zeta. \ (63)$$

Notice that

$$u_n (x, t) = \sum_{i=1}^{n} \phi_i (x, t). \ (64)$$

Plugging the norm on the Eq. (63), and by the assist of Eq. (58), we get

$$\|\phi_n (x, t)\| \leq \frac{(1 - \alpha)}{B(\alpha)} \eta \|\phi_{(n-1)} (x, t)\|$$

$$+ \frac{\alpha}{B(\alpha) \Gamma (\alpha)} \eta \int_0^t \|\phi_{(n-1)} (x, \zeta)\| d\zeta. \ (65)$$

By the assist of the above result, we prove the following theorem.

**Theorem 6.** The solution for Eq. (51) will exist and unique if there exist a $t_0$ then

$$\frac{(1 - \alpha)}{B(\alpha)} \eta + \frac{\alpha}{B(\alpha) \Gamma (\alpha)} \eta < 1.$$

**Proof.** Let us consider the bounded function $u(x, t)$ satisfying the Lipschitz condition. Then, we get by Eq. (63) and Eq. (55), one can get

$$\|\phi (x, t)\| \leq \|u_n (x, 0)\| \left[ \frac{(1 - \alpha)}{B(\alpha)} \eta + \frac{\alpha}{B(\alpha) \Gamma (\alpha)} \right]^n. \ (66)$$

Therefore, for the obtained solutions, continuity and existence are verified. Now, to prove the Eq. (66) is a solution for Eq. (51), we consider

$$u(x, t) - u(x, 0) = u_n (x, t) - \mathcal{K}_n (x, t). \ (67)$$

Now, we consider

$$\|\mathcal{K}_n (x, t)\| = \left\| \left( \frac{1 - \alpha}{B(\alpha)} \right) (G(x, t, u) - G(x, t, u_{n-1})) \right\|$$

$$= \frac{\alpha}{B(\alpha) \Gamma (\alpha)} \int_0^t (t - \zeta)^{\alpha-1} \|G(x, \zeta, u) - G(x, \zeta, u_{n-1})\| d\zeta$$

$$\leq (1 - \alpha) \frac{\eta}{B(\alpha)} \|u - u_{n-1}\|$$

$$+ \frac{\alpha}{B(\alpha) \Gamma (\alpha)} \eta \|u - u_{n-1}\| t. \ (68)$$

Similarly, at $t_0$ we can obtain

$$\|\mathcal{K}_n (x, t)\| \leq \left( \frac{1 - \alpha}{B(\alpha)} + \frac{\alpha t_0}{B(\alpha) \Gamma (\alpha)} \right)^{n+1} \eta^{n+1}. \ (69)$$

As $n$ tends to $\infty$, then $|\mathcal{K}_n (x, t)|$ approaches to 0 with respect to Eq. (69).

$$u(x, t) - u^*(x, t)$$

$$= \frac{(1 - \alpha)}{B(\alpha)} (G(x, t, u) - G(x, t, u^*))$$

$$+ \frac{\alpha}{B(\alpha) \Gamma (\alpha)} \int_0^t \|G(x, \zeta, u) - G(x, \zeta, u^*)\| d\zeta. \ (70)$$

The Eq. (70) simplifies on applying norm,

$$\|u(x, t) - u^*(x, t)\|$$

$$= \left\| \frac{(1 - \alpha)}{B(\alpha)} (G(x, t, u) - G(x, t, u^*)) \right\|$$

$$+ \frac{\alpha}{B(\alpha) \Gamma (\alpha)} \eta \left\| \int_0^t (G(x, \zeta, u) - G(x, \zeta, u^*)) d\zeta \right\|$$

$$\leq (1 - \alpha) \frac{\eta}{B(\alpha)} \|u(x, t) - u^*(x, t)\|$$

$$+ \frac{\alpha}{B(\alpha) \Gamma (\alpha)} \eta t \|u(x, t) - u^*(x, t)\|. \ (71)$$

On simplification

$$\|u(x, t) - u^*(x, t)\|$$

$$= \left( 1 - \frac{\alpha}{B(\alpha) \Gamma (\alpha)} \eta t - \frac{(1 - \alpha)}{B(\alpha)} \eta \right) \leq 0. \ (72)$$

From the above condition, it is clear that $u(x, t) = u^*(x, t)$, if

$$\left( 1 - \frac{\alpha}{B(\alpha) \Gamma (\alpha)} \eta t - \frac{(1 - \alpha)}{B(\alpha)} \eta \right) \geq 0. \ (73)$$
4. Results and discussion

In this section, we consider two cases as mentioned above to analyze the hired model with a hole, and presented in Figure 1. In the first case
for $\beta = 2$, the behaviour of $b(x)$ is a lock-like reciprocal of bell-shape and also sharp at the bottom. For the second case (i.e., $\beta = 8$), the hole at the bottom is more flattened and wider. In the present investigation, we consider constant wave speed $c \approx \sqrt{g \times h} = \sqrt{9.8}$ with a mean water depth of the sea $h = 1$. For $\beta = 2$, the nature of archived results for the FF-KdV equation with different distinct fractional operator and fractional-order is captured respectively in Figures 2 and 3. In Figure 3 we can observe that at $x = -2$ and 2 the behaviour of water evaluation is overlapped for different value of $\alpha$ and moreover the change in time shows stimulating variation in the behaviours. The nature of the water elevation with sea bed topography with $\beta = 2$ and 8 are presented in Figures 4 and 7 for different Froude number in order to understand the importance of $b(x)$ and $\beta$ in the obtained solution at the particular values of the time. In the same manner, for $n = 8$ surfaces for an obtained solution with a distinct fractional operator is cited in Figure 5. The response of $\varphi$-HATT solution for FF-KdV equation with distinct $\alpha$ is dissipated in Figure 6 for $\beta = 8$. In this case, also we can notice the huge change in the behaviours with a small change in time with fractional order.

The considered method is highly noticeable for the parameters associated with the algorithm and which help to make more convergence (they are proposed based on the topological concept). To illustrate the nature of the solution obtained with homotopy parameter ($h$), the $h$-curves are plotted.
A computational approach for shallow water FKdV equation with three fractional operators

\[ \alpha = 1 \quad \alpha = 0.75 \quad \alpha = 0.50 \]

\[ t = 0.1 \]

Figure 6. Response of obtained solution with distinct \( \alpha \) and time at \( n = 1, \ h = -1, \ \beta = 8 \) and \( F_r = -1 \).

\[ \alpha = 1 \quad \alpha = 0.75 \quad \alpha = 0.50 \]

\[ t = 0.2 \]

\[ t = 0.5 \]

\[ t = 1 \]

Figure 7. Nature of water elevation with \( b(x) \) at \( n = 1, \ h = -1, \ \beta = 8 \) and \( \alpha = 1 \).

Figure 8. \( h \)-curves for \( q \)-HATT solution with distinct \( \alpha \) when \( n = 1 \) and \( t = 0.01 \) with

(a) \( \beta = 2 \) at \( x = 1 \) and (b) \( \beta = 8 \) at \( x = 5 \).

with different \( \alpha \) for both cases (i.e., \( \beta = 2 \) and 8) and are respectively captured in Figure 8. Line flat segment designates the convergence providence of the solution.

5. Conclusion

In this study, the \( q \)-HATT is applied lucratively to the analyzed effect of parameters associated with

the method (rigid bottom topography and Froude number) by finding the solution for an arbitrary order shallow water forced KdV equation describing the free surface critical flow over a hole. The derived results show the effect of rigid bottom topography and Froude number with change in time and space with different fractional order. By using the considered model, two distinct kinds of hole are analyzed and which shows that for \( \beta = 2 \)
exhibits a hole in inverse-bell shape and at $\beta = 8$ shows a hole has a sharp edge on two-sides and also it has a flattened base. The condition is derived for the considered model to illustrate the existence and uniqueness within the frame of fixed-point theory using Banach space. The effect of three fractional operators is presented and other effects are illustrated with respect to the Caputo operator. These fractional operators are playing a vital role in generalizing the models associated with power-law distribution, kernel singular, and non-local and non-singular (respectively, Caputo, CF and AB operators). Finally, the present study is to demonstrate the effect of fractional order, parameters associated with models as well as methods with their corresponding consequences.
